

Task Manager App

A calendar-centric life dashboard: tasks, fitness, medication, payments, and expenses in one place

What's new in v2:

- Fitness module fully specified (AI plan chatbox, plan/actual reconciliation)
- Reminders depth (recurrence, escalation ladder)
- Home calendar visual system (density-coded month view)
- Onboarding flow, including multi-profile caregiver accounts
- Caregiver monitoring privacy model
- Consolidated open risks & phasing

1. Core concept

The app is a calendar-centric task manager. The **Home screen is a live calendar**, and four separate life-domain modules feed into it: **Fitness**, **Reminders** (Pill, Payment, Appointment, Custom), and **Expense**. The calendar is strictly an **aggregator and preview layer** — it never owns or duplicates module data.

2. Navigation structure

Tab	Role
Home	Calendar view. Aggregates and previews entries from all other modules.
Fitness	Workout logs, goals, and AI-assisted plan generation.
Reminders	Pill, Payment, Appointment, and Custom — grouped under one tab, each with its own icon.
Expense	Categorized spending ledger; rolls up into daily, weekly, and monthly totals.

Pill and Payment share a tab rather than getting their own, since structurally both are the same object type (a due date/time + a "mark done" action) differing only by domain, not structure.

3. The "+" add flow

Module-first, always — never one flat combined list. Global "+" shows module picker, then that module's categories. Tapping a **specific date** on Home shows module options directly (Pill, Fitness, Payment, Appointment, Custom) with the date pre-filled — the primary, fastest path for most entries.

4. Reminders module

4.1 Pill

MVP: manual entry v2: auto-lookup

Functions as a lightweight medical ID for elderly users to show a doctor/pharmacist what they take. **Fields:** name, dosage, time(s)/day, expiry, photo. Auto-lookup of drug details from a database is deferred to v2 — manual entry alone already solves the core use case.

4.2 Payment / Bill

Fields: payee, amount, due date, recurring flag. Links into Expense — see Section 6.3.

4.3 Appointment

Kept deliberately simple — title, location, time only. Shares the same recurrence and notification system as every other reminder type; simplicity here is about fields, not capability.

4.4 Custom

User picks any emoji from their device keyboard to represent a freeform task, avoiding the need to predict every category in advance. **Same-day grouping:** reusing an emoji on a date already used doesn't create a duplicate entry — it groups as another task under that emoji's bucket, each with a distinct timestamp. The calendar shows the emoji once with a count badge (e.g. "👉 ×3"); tapping expands the list. **Tracking:** set per item at creation as either streak/checklist or numeric.

4.5 Reminder timing — module-specific

Module	Timing control
Pill	Times-per-day picker
Payment	Days-before-due picker
Fitness / Custom	Simple time picker

4.6 Recurrence

Two paths, both user-controlled: **quick presets** (next day, 2 days after, after 3 days, same day next week, same day next month) for the common case, and **full custom flexibility** for irregular patterns — e.g. next month on the 2nd, then again 2 months later on the 4th. Custom recurrence is effectively a list of individually-set future occurrences rather than a single repeat-interval rule, so editing later means adjusting individual dates rather than one master rule.

4.7 Missed / overdue — escalation ladder

Loud by default (matches the safety-first principle used throughout — silently letting a missed dose disappear is the worst outcome), with a per-user toggle to quiet it down.

Step	Trigger	Action
1	Scheduled time	Normal notification
2	+5 minutes, still unactioned	Stronger alert (different sound / persistent)
3	+7 more minutes (~12 min total), still unactioned	Distress notification sent to the linked caregiver, if one exists

Missed pills specifically are visible to a linked caregiver, tying this directly into the monitoring system defined in Section 8.

5. Fitness module

5.1 Object types

Workout log (retrospective — what was done) and **Goal** (prospective — what's being aimed for). Goals drive the calendar forward: planned workout days appear on the calendar in advance, keeping Fitness consistent with every other module, where the calendar shows what's scheduled to happen, not only what already happened.

5.2 Plan creation — two user-controlled paths

- **AI-assisted chatbox** — gathers fitness level, goal, equipment, and available days conversationally, then **proactively drafts a plan** once it has enough information (rather than an open-ended chat with no clear end point). The user can keep refining the draft after it's generated. Diet-plan generation was considered and removed from scope — the chatbox covers workout routines only.
- **Fully manual entry** — user builds a multi-day workout plan themselves, no AI involved.

5.3 Plan vs. actual reconciliation

Resolved: once a user edits an AI-suggested workout, the *edited* version becomes the real plan — the AI's original suggestion is a first draft only. Actual logged results are then compared against that edited plan for goal and streak tracking (e.g. "planned 20 min, did 25").

5.4 Deferred scope

v2 Wearable / step-counter sync (Google Fit, Apple Health, fitness bands). MVP is manual logging only.

6. Expense module

6.1 Categories

Food, Transport, Bills/Utilities, Shopping, Health, Other.

6.2 Calendar integration

Tapping a date shows that day's total spend. A dedicated gap/section after each month shows weekly expense breakdowns (e.g. days 1-7 total). Day cells in the grid itself stay clean — no in-cell numbers, see Section 7.2.

6.3 Payment ↔ Expense linking

When a Payment is marked paid, it auto-creates a linked Expense entry (Bills category) to prevent double-counting — the Payment reminder is the source of truth. A per-payment opt-out toggle ("count this toward my expenses?") handles cases like paying on someone else's behalf. Both paid and unpaid amounts count toward the monthly total (unpaid = committed/upcoming spend), recommended to be visually distinguished (solid vs. outlined).

7. Home calendar — visual system

7.1 Default view

Month view is the landing screen. Dates dive into full detail on tap.

7.2 Density-coded cells (no icons in the grid)

Rather than cramming five different signal types (pill, payment, appointment, custom, expense) into a tiny cell, each date is shown as a colored shape reflecting how busy that day is:

Task count	Color	Edge style
0 (no tasks)	Translucent / neutral	—
1-4	Green	Soft, rounded edges
5-7	Orange	Medium
8+	Red	Rough, sharper edges

Edge shape is a deliberate accessibility layer alongside color — red/green alone is the most common form of color blindness, so busyness stays readable without relying on color perception.

7.3 Expense display

Daily and monthly expense figures are never shown inside the grid cells themselves (that would compete visually with the density signal). They live behind the tap-in detail view and in the dedicated end-of-month weekly-breakdown section.

8. Onboarding & account structure

8.1 Signup

Collects name, age, location permission, phone number, and email. Offers a separate setup path for **"for a child"** or **"for an elderly person"** — i.e. a caregiver setting the app up on someone else's behalf.

8.2 Forced module setup

New users are forced through at least **2 modules** before a skip option appears — fixed as **Pill + Payment**, the two with the highest real-world consequence if skipped. Which modules are forced can vary by profile type based on real-life risk assessment (a child profile's risk profile isn't identical to an elderly profile's). Users classified above 45 (or elderly profiles) are forced through **all 4** modules.

The walkthrough offers 2 choices: enter real data, or watch a pre-recorded demo video.

8.3 Multi-profile / caregiver accounts bigger than onboarding — see Section 9

A single login can manage multiple profiles (self, a child, an elderly parent). This is the structural backbone that makes caregiver monitoring (Section 9) possible.

9. Caregiver monitoring

Resolved design:

- **Visibility:** the caregiver sees full detail — medication names, dosages, expiry — not just a pass/fail status signal, since full detail is what's actually useful in an emergency.
- **Consent:** the monitored person can always see that they are being watched. Monitoring is never silent.
- **Setup:** the monitored person must approve monitoring before it begins — a caregiver cannot add someone and start watching unilaterally.
- **Age-based privacy:** if a monitored child profile is above 18, monitoring access is restricted to respect that person's privacy going forward.

10. Open risks & unresolved items

Multi-profile account architecture is a real project, not a feature toggle. Profile switching, permission scoping by relationship type, and age-based access changes need dedicated design attention beyond what's captured here.

Elderly-simplicity vs. system depth. The app now has real depth (AI fitness chat, emoji-based custom grouping, multi-profile caregiving) layered on top of a design partly aimed at elderly ease-of-use (the Pill medical-ID angle). Needs a UX pass once real screens exist to confirm the simple path (add a pill, view calendar, get reminded) never requires touching the complex layers underneath.

Notification delivery engine. The escalation ladder's timing is now defined (Section 4.7), but the underlying push-notification infrastructure to actually deliver it reliably is still a build item, not just a design one.

11. Deferred / v2 scope — consolidated

Item	Why deferred
Pill drug-database auto-lookup (name/scan → auto-filled details)	Requires integrating an external medicine database — real subsystem, not a form field.
Fitness wearable / step-counter sync	Real integration project (Google Fit / Apple Health / device APIs).
Multi-profile caregiver account architecture	Core privacy/consent rules are defined (Section 9), but the full permission-scoping system is bigger than a first release.

12. Still to design

- Detailed UX pass confirming the "simple path stays simple" principle (Section 10).
- Full notification delivery/infrastructure design.
- Visual mockups for each module's detail screens (this spec covers structure, not pixel-level layout).
